Four Dimensions of Learner Autonomy

Paul Bouchard¹
Concordia University (Montreal)

Mediated learning environments can provide Some authors (Kegan, 1986; Perraton, 1983), pointed out that printed material mailed to a distant location increased pressure on the learners to set their own schedule and to work around deadlines imposed by the teaching institution. This feature led to the supposition that distance learning requires some higher degree of learner autonomy than traditional classroom instruction. Indeed, lack of autonomy was considered the main reason why students failed or discontinued their programs.

Another feature of Distance Education was identified as the constraint imposed on institutions to produce a standard learning program that will be followed by all learners in the same sequence, usually within a set of prescribed deadlines (Holmberg, 1986). This institutional standardization, inevitably, is then passed on to the learner. In this respect, distance learning environments can be said to constrain the expression of autonomy among learners and instructors alike.

The question of whether a specific learning environment will support or hinder the expression of autonomy is an important one for adult educators. Indeed, it is our view that the quality of any learning environment is to a significant extent dependent on the degree to which that environment acknowledges the need to support learner self-direction. In one influential work, Candy (1991) defines self-direction in these terms:

*Being able to pursue a learning goal with equal vigour and determination without being adversely affected by external factors including the increase or decrease of rewards for pursuing or attaining the goal (…)*

And further:

*Being aware of alternative choices, both as to learning strategies and to interpretations or value positions being expressed, and making reasoned choices about the route to follow in accordance with personally significant ideas and purposes.*

Interestingly, these quotes point to very different aspects of learner autonomy, the central one being the control that the learner exercises over the various aspects of learning, beginning with the decision to learn or not to learn. But as Candy points out, there are other specific areas where learner-control can be exercised.

The first are the motivational-intentional forces that drive the learner to apply some determination (or “vigour”) to the act of learning. This area embodies the conative functions of learning which are at the foundation of learner initiative, motivation and

¹ paul@education.concordia.ca
personal involvement. Most often, adult learners harbor life-goals that are related, but distinct from the actual learning goals (e.g. career advancement, good parenting or better health), as part of the conative baggage they carry. Other possible drives include the pleasure one derives from the act of learning in itself, and the satisfaction obtained from becoming part of a particular culture of knowledge (Houle, 1961).

The second set of elements that define learner autonomy involve control over the “nuts-and-bolts” of the act of learning, such as defining learning goals, deciding on a learning sequence, choosing a workable pacing of learning activities, and selecting learning resources (Hrimech & Bouchard, 1998). These elements can be grouped under the heading of the algorithmic aspects of learning. In traditional learning environments, most of the algorithms are the responsibility of a teacher or a teaching institution. Learning goals, student workload and methods of evaluation are usually stipulated at the outset and little participation in their formulation is expected from the learner. Derogation from this approach entails devolving to the learner, on top of the expected “learning tasks”, at least some of the “teaching tasks” normally reserved for the instructor. In this sense, we can say that autonomy is directly related to the number and magnitude of the “teaching tasks” that are appropriated by the learner (Tough, 1965). Most mediated learning environments require such participation from learners, albeit to different degrees and with varying results.

Until recently, learner control was necessarily limited to these two sets of features, conative and algorithmic. After deciding whether, what, and how to learn, one had covered all areas where it was conceivably possible to exercise some degree of learner autonomy. Now with the proliferation of learning environments that include mediated instruction materials, exponentially available learning resources, new means of communication, and a marketplace literally exploding with learning opportunities, two other components of learning emerge as possible areas where learner control may exercised, namely the semantics employed by the new media, and the emerging economics of the knowledge marketplace.

The traditional medium for encoding, storing and disseminating knowledge was to provide access to print materials through libraries, mail-order programs, or custom-printed resources. Today, learning materials include very diverse media which may share very few features with printed text. For example hypertext, asynchronous messaging and electronic whiteboards each possess their own set of codes and behaviors that are inconsistent with the linear quality of print. Furthermore, the manner in which each new medium is utilized by instructors and learners varies to some extent, leading to further diversification in the perception of their semantic possibilities (Garrison, 2000). For example, hypertext can be used as a way to link course materials to outside resources, or as an inherent part of the material to be learned, or then again as non-compulsory enrichment to the basic text such as illustrations or diagrams to be viewed when needed. Hypertext can be perceived as a convenient way to store and retrieve information, or as a bothersome irritant leading to feelings of frustration in the presence of overwhelming amounts of poorly organized data. Because each environment offers its own set of communication pragmatics and its own approach to using them, we can say that the semantic components are an integral part of the learner’s experience, and as such offer opportunities to enhance or deter learner autonomy.
Learning is no longer the reserved province of traditional institutions such as schools or colleges. Indeed, it is now acknowledged that universities find themselves in direct competition not only with each other, but with a multitude of offerings from a thriving marketplace. (Moore & Kearsley, 1996). An important component of a learning environment is the perceived economic value of its knowledge in the marketplace, either as an asset for finding employment or as a means of production in the knowledge economy. Based on these considerations, learners must not only decide why and what to learn, but also where to learn it. Environment, but most importantly the choice rests on the perceived cost-benefit ratio and opportunity costs which are generated by each alternative. In this context, we can observe that the economics of learning are emerging as an important component of any learning environment.

Thus, learner autonomy can be divided in four areas of learner control: conative, algorithmic, semantic and economic. One useful feature of this representation is that it makes it possible to explore learner perceptions within different learning environments, while retaining a constant framework for analysis.

**METHODOLOGY**

Open-ended interviews were conducted with 13 adult students registered in online courses in Psychology, Finance, Education, and Political Science. Questions were formulated to explore the four areas of learner autonomy, using everyday terminology familiar to the students. Interviews were taped, transcribed, coded and analyzed using standard content analysis techniques. Coding was done by grouping units of meaning under tentative headings, and then combining the headings under generic titles using an emergent design method. The factors that determined the students’ perception of each learning environment appear in Figure 2. They are categorized as: Interaction; Structure, Value, Context, and Media

**FINDINGS**

One of the first things that became apparent during the interviews was the diversity in the likes and dislikes of individuals concerning the various components of the learning environments. All courses were designed using online course materials, a messaging device and a textbook. Some used hyperlinks to other web-based resources, and none included classroom or face-to-face meetings. The individual preferences were polarized around the use of media, the course structure and the value of course content. Predictably, about half of the students said it took some effort to prevent inertia when facing the prospect of doing tasks online, in the absence of an imposed schedule.

**Interaction.** The portion of the course grade allotted for participation in on-line discussion groups varied between 0% and 40%. In the groups where there was less pressure to ‘participate’, students felt that the interaction was more meaningful and that they were more in ‘control’ of the environment. From the students’ responses, it appears that instructors did not attach any weighting to the quality or tone of the interactions. Some students felt that the imposition of online discussion was superfluous, but nevertheless felt their learning was validated when read by others. Some students felt uncomfortable at the idea that the instructor had access to the messages, which prompted the use of alternative means of communication between students – private email and
telephone conversations. In one instance, the instructor’s failure to moderate a somewhat incendiary discussion on Middle-East politics dissuaded other students from participating. Interaction also occurred between students and TAs, technicians and, more rarely, professors. Students enrolled in a full-year course reported the growth of a sense of learning community around the 4th month of interaction, while single-term students did not. Posting messages to a discussion group was perceived as less threatening, and therefore more accessible, than voicing comments in a classroom. One student complained that there is no real connection to others when talking on-line – “you never get to ‘know’ anyone”.

Structure. A few students who had a personal interest in their course topic spontaneously searched for alternative learning resources but overall, this was not a prevalent practice. All courses except one had set very specific objectives, thereby circumventing student participation in their formulation. When a learning goal was stated in general terms, mature students more readily established links with their own experiences and interests. Evaluation was done in much the same way as in classroom environments, participation in discussion groups being graded in lieu of attendance. Overall, students had difficulty evaluating their own learning, stating instead that they earned their grade simply by conforming to the course-work requirements. Students with poor performance tended to blame the “lack of clarity” of the course objectives.

Students admitted readily that they chose an on-line course because of the flexibility it afforded in their schedule. However, some found the prescribed pacing too slow, while others found it somewhat daunting, especially when assigned weekly readings – thus, scheduling became more of a problem than anticipated. The requirement to participate in online discussions was perceived as additional workload that would have been less demanding in classroom interaction. The detailed program structure found in all but one of the on-line courses was perceived to make the learning tasks more manageable, as they were relieved of any ambiguity.

Value. Students can be placed in two groups according to the criteria they used to establish the value of their learning. The first group derived their estimation from the potential usefulness of their newly acquired knowledge in some immediate area of their lives, either by providing tools for better understanding world issues or financial matters, or by developing skills that apply to family relationships or the workplace. The second group was typically concerned with completing a university degree and selecting eligible courses for their anticipated convenience or easy workload. Interestingly, several students admitted opting for on-line courses assuming – wrongly they soon discovered – that they would entail a flexible schedule and a less demanding productivity. Some of the derived benefits were discovered as learning occurred throughout the courses. Others were identified as unanticipated spin-offs, such as developing better writing or computer skills. One student pointed out that his workplace offered a similar course package, featuring a better design and a lower cost, but that it could not be credited towards his university degree.

As in many institutions, the actual per-credit cost to the student is considerably higher for the on-line version of a course. Students generally accepted this fact with some resignation, but could not explain the disparity. One student realized too late that he
could have learned independently, at a much lower cost, everything that he learned in his course. Two other students acknowledged that they had chosen the institutional avenue in order to access the university’s sophisticated computer labs.

**Context.** Students were asked about the reasons they decided to enroll in their course, and why they chose the on-line version of the course. Conative factors such as desire to understand family issues, and wish to improve work performance were mentioned by mature and non-degree students only. Reasons for choosing the on-line version of the course were mostly linked to personal, family and work situations. Somewhat ironically, the same factors were identified as barriers to achievement in the on-line course. The institutional context also was perceived to play a role, beginning with the fact that two versions of the course were offered by the institution, that the on-line version was higher priced but available, and that the absence of in-class meetings seem to motivate the instructors to increase student workload.

**Media.** In a previous study (Bouchard & Kalman, 1998), low computer literacy was identified as a barrier to distance learning. Here, students all had achieved reasonable competency at using computers. Some difficulties were encountered however with the consistency of access to the online environment. There were frequent system crashes and technical help was not always available. From the delivery point of view, the emphasis was placed on completing course assignments and little attention was paid to students’ efforts to learn how to navigate within the system and outside. Some features of the courseware were used routinely, such as messaging and on-line exams, while others were rarely or not used (file transfer, self-corrected testing, live chat, transfer of images or animated gif files, etc).

**DISCUSSION**

The purpose of this study was to obtain from the learner’s perspective some indication of the factors that encourage or deter from the development of self-direction in mediated learning environments. In light of the data collected, it is possible to make some recommendations that relate to the conative, algorithmic, semantic and economic dimensions of learner autonomy. Further analysis will allow us to produce a more detailed classification, but for now we will limit ourselves to a number of recommendations that are supported by our data. This information should be useful for planners who value, beyond the attainment of academic standards, the capacity for self-direction as a central goal of education.

First, it should be noted that students embark in on-line courses with various expectations, ranging from fairly reasonable to confused. Efforts should be made towards correcting the most common misunderstandings, such as the expectation that on-line courses are easy, require less time and demand less participation – before enrolment. Some allowance should be made at the beginning of a session for learning the navigation and software tools that will be useful for learning. When possible, face-to-face meetings or other devices seeking to personalize the learning environment should be planned in order to reduce feelings of alienation. Online discussions should be structured around guidelines and clear criteria should be set to evaluate the quality, rather than quantity, of participation. Instructors should attend to online discussions but refrain from acting as
one of the participants. Students’ work can be validated by peers through feedback given on short warm-up assignments. Students can be encouraged to explore alternative sources of documentation outside the confines of the on-line device, and to establish links with their own personal areas of interest. Reasons for pricing on-line courses in a higher bracket should be made public by the institution, or that practice should be discontinued. Planners should be aware of the added time constraints imposed by on-line participation in discussion groups, testing and other interactions. Students can be encouraged to explore the possibilities offered by the institutional and other software packages, and not limit themselves to those functions used by the instructor.

On-line and other mediated learning environments offer much potential for supporting the development of self-directed learning skills, but alas they can also be powerful deterrents. Realizing that potential – and reducing the deterrent effect – are possible if educational planners consider it an important criterion when making instructional design decisions.
